Abstract of no bolisiq bas of its insigned to no college

MxaJ is a protein of unknown function encoded by mxaJ in the mxaFJGI operon. We have constructed a mxaJ mutant of M. extorquens with a deletion which does not affect transcription of downstream genes. It contained cytochrome c_L (MxaG), but neither subunit of methanol dehydrogenase (MxaF and MxaI). MxaJ is probably involved in processing this enzyme. We have sequenced the region between mxaFJGI and five other methanol oxidation genes, mxaACKLD; it includes one open reading frame (mxaR) and a possible second open reading frame (mxaS), demonstrating the presence in M. extorquens of the following gene cluster: mxaFJGIR(S)ACKLD.

Keywords: Methanol oxidation; Methylobacterium extorquens; mxaFJGIR(S)ACKLD operon

1. Introduction

In Gram-negative methylotrophic bacteria, methanol is oxidised by methanol dehydrogenase (MDH), a quinoprotein with an $\alpha_2\beta_2$ tetrameric structure, containing pyrrolo-quinoline quinone (PQQ) and a calcium ion at its active site. Its electron acceptor is a specific c-type cytochrome, usually designated cytochrome c_L [1,2]. There are at least 30 methanol oxidation genes, arranged in 5 clusters; these include the genes involved in PQQ biosynthesis [2]. The genes encoding the α and β subunits of MDH (mxaF and β) and cytochrome c_L (mxaG) are situated in an operon together with mxaJ [3–5]. This encodes a 30-kDa periplasmic protein suggested to be either a

third (non-essential) subunit of MDH [6] or a molecular chaperone [5].

(0,4%) as described in [12]. Supplements were added

The genes mxaFJGI are transcribed from a promoter upstream of mxaF; this is the only promoter so far definitively identified in a methylotroph [4,7]. About 2 kb downstream from mxaI in Methylobacterium extorquens is another cluster of genes (mxaACKLD) some, if not all, of which are involved in the insertion of calcium into the active site of MDH [8,9]. The mxaACKLD cluster has not been described in Paracoccus denitrificans, but immediately downstream of mxaI in this organism there is another gene (mxaR) and the 3' end of a putative open reading frame subsequently designated mxaS [5,9]. Studies with mxaJ mutants have shed little light on the role of this gene [5,10] because interpretation of the phenotype is difficult as the mutations may affect expression of neighbouring genes.

In this paper we describe the construction of a mutant of *M. extorquens* with a deletion in *mxaJ* which does not have any confusing effects on the transcription of downstream genes. We have also completed the sequencing of the region between *mxaI* and *mxaA*; this indicates that there are 10 or 11 genes in this cluster, in the order *mxaFJGIR*-(S)ACKLD.

2. Materials and methods

The bacterial strains and plasmids used in this study are shown in Table 1. *Escherichia coli* strains were grown at 37°C in LB medium [11]. *M. extorquens* AM1 was grown at 30°C on minimal salts medium containing 0.5% methanol plus methylamine (0.4%) as described in [12]. Supplements were added to the growth medium when appropriate to give the following final concentrations: for solid medium kanamycin, 50 μg ml⁻¹; ampicillin, 50 μg ml⁻¹; tetracycline, 20 μg ml⁻¹: for liquid medium antibiotic concentrations were halved. When X-gal was used, 20 μl of a 50 mg ml⁻¹ stock solution in dimethylfor-

mamide (Promega) was spread on each agar plate just before plating.

M. extorquens chromosomal DNA was purified as described previously [13]. The Wizard miniprep DNA purification system (Promega) was used for small-scale plasmid isolation from E. coli. Largescale plasmid preparation by the alkaline lysis method, DNA manipulations, transformation of E. coli, and agarose gel electrophoresis were done as described previously [11]; restriction enzymes were obtained from Promega or New England Biolabs. Southern blotting was done as described in the Hybaid Limited Hybridisation Guide (1992). Probes were labelled with [α-32P]dCTP and random hexamers using the Prime-a-Gene kit (Promega). Bacterial matings were done as described in [13] except that donors and recipients were grown as lawns on solid medium. The bacteria were scraped off, mixed in a 1:5 donor:recipient ratio and plated onto minimal salts medium containing methanol and methylamine.

Single and double stranded DNA was sequenced by the dideoxy chain termination method using the Sequenase® version 2.0 kit (USB) with the 7-deazadGTP nucleotide mixtures, using specific custommade primers. Oligonucleotide primers were synthe-

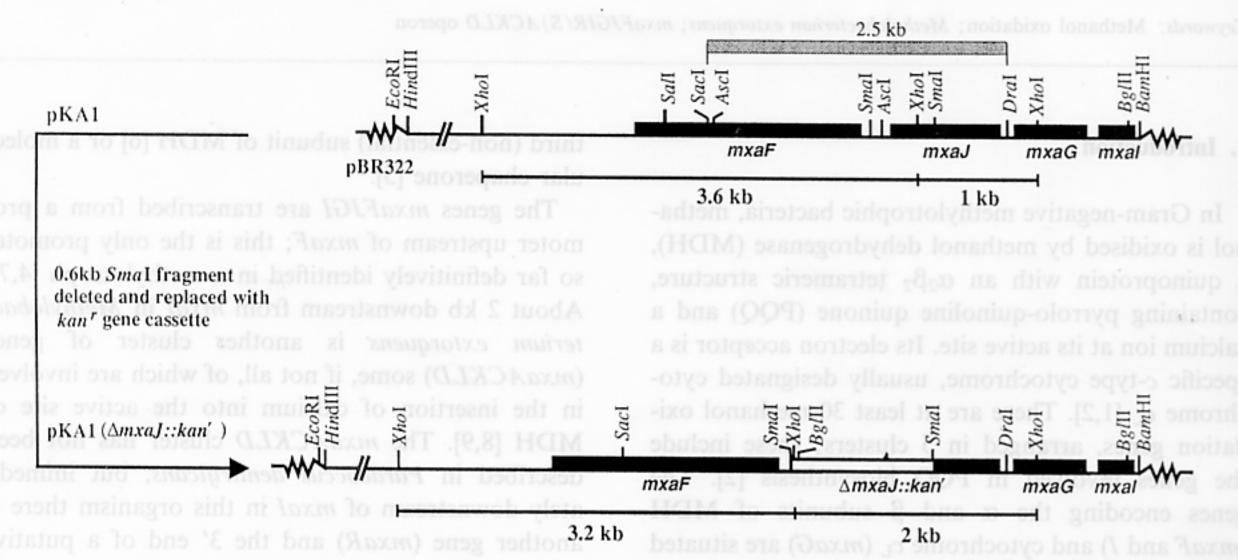

Fig. 1. Restriction map of the mxaFJGI operon from M. extorquens and strategy for construction of the mxaJ deletion mutant. The map is not strictly to scale. Transcription of the mxa genes is from left to right. The 0.6 kb deletion within mxaJ is shown. The white box indicates the kanamycin resistance reporter gene replacing the deleted DNA. The probe used for Southern hybridization is shown as a grey box. Bars below each restriction map show the wild-type and mutant XhoI fragments hybridizing to the probe. The EcoRI site is within the pBR322 vector sequence. The XhoI fragments from the wild-type (1 kb+3.6 kb) and the KAJ7 ($\Delta mxaJ$: kan^{r}) mutant sequences (2 kb+3.2 kb) hybridised with the T_4 probe in Southern blotting experiments as expected.

sised, with the trityl group attached, using a model 391 PCR-MATE[®] DNA synthesiser on a 40 nmole scale. The synthetic DNA was purified using oligonucleotide purification cartridges (Applied Biosystems). Some compressions were resolved by adding 40% formamide to the sequencing gels. DNA fragments were cloned into M13mp18 in one direction and into M13mp19 in the opposite direction, to facilitate sequencing of both strands. The sequence was also confirmed in both directions by automated DNA sequencing on a Li-Cor model 4000 sequencer. DNA and protein sequences were analysed using PC/ Gene (IntelliGenetics) and DNASTAR (DNASTAR Inc., Wisconsin, USA) and compared with sequences in the GenBank, Swiss-Prot and Prosite databases using the FASTA and BLAST programs [14,15].

Respiration [16], cell extract preparation and MDH assays [12], SDS-PAGE of cell extracts and haem staining [17] were done as previously described using at least two independent cultures. For SDS-PAGE (for protein analysis), cell extracts (150 µg

protein) were mixed with 0.2 volumes of loading buffer, boiled for 5 min and spun briefly before loading. For SDS-PAGE when subsequently haem staining, samples were mixed with loading buffer in the absence of β -mercaptoethanol and were loaded without boiling. For Western blotting, proteins were transferred from SDS-PAGE gels to nitrocellulose using the Bio-Rad mini Trans-Blot system. Rabbit anti-holoMDH, anti-MDH β -subunit and anti-cytochrome c_L were used as primary antibodies. Horse-radish peroxidase-conjugated donkey anti-rabbit IgG (Bio-Rad) was used as secondary antibody.

3. Results and discussion

3.1. Construction and characterisation of a marked, non-polar deletion mutant (mutant KAJ7) in mxaJ in Methylobacterium extorquens

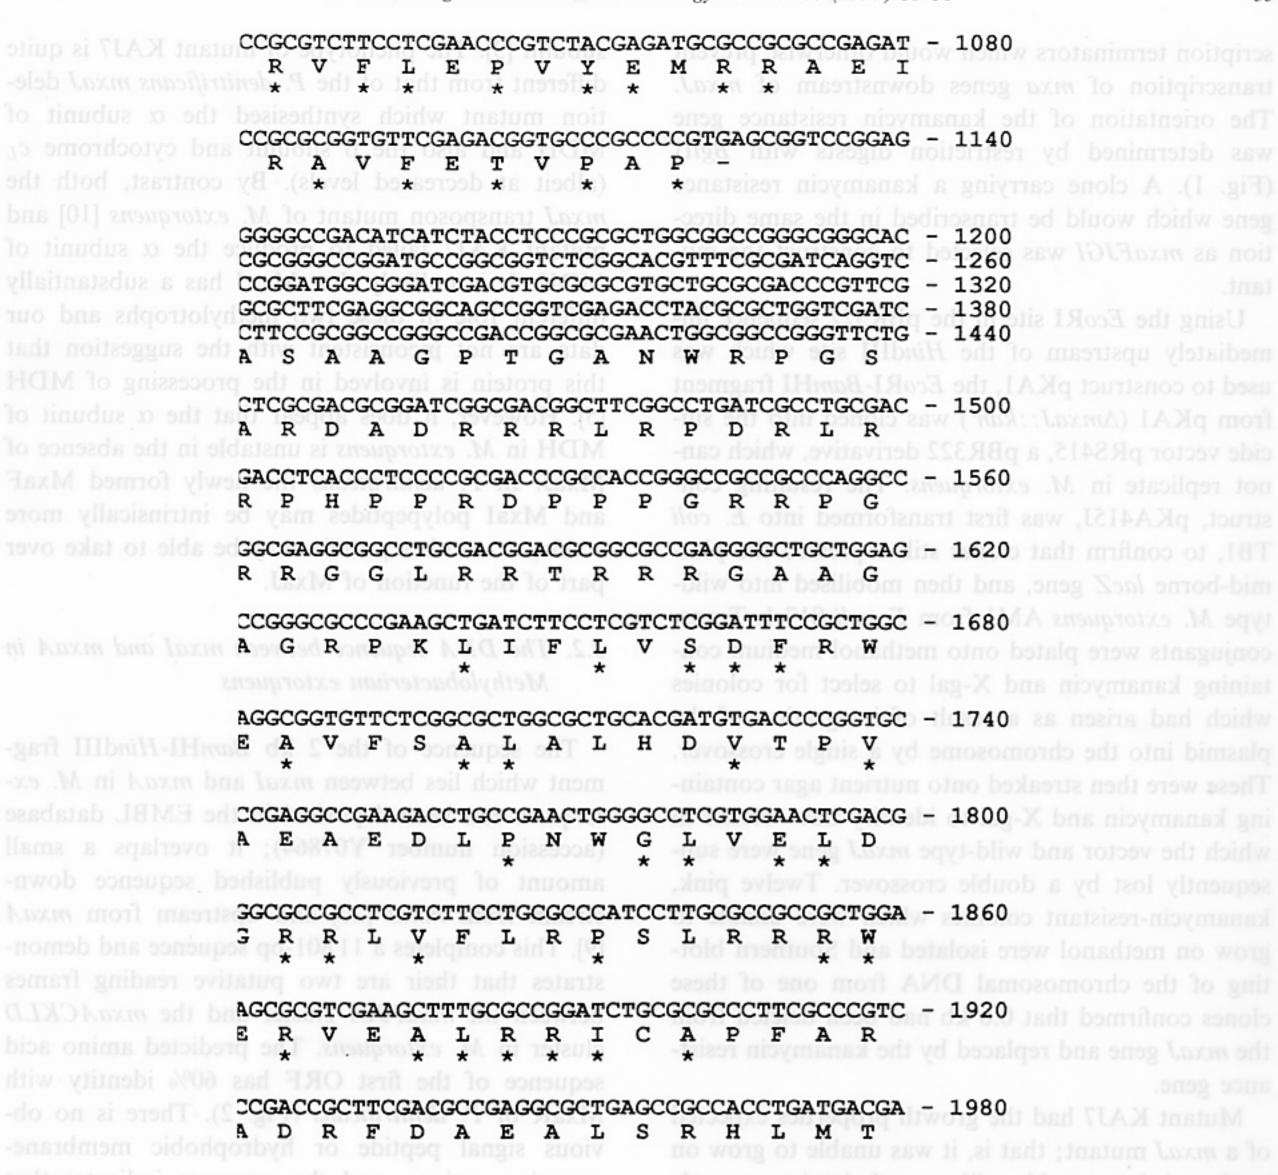

Fig. 2. The nucleotide sequence of the region between mxaI and mxaA in M. extorquens. Nucleotides 1–344 and the sequence downstream of 1886 have been described previously [9,20]. A possible Shine-Dalgarno site upstream of mxaR is underlined. The protein sequence labelled in parentheses (MxaS) represents the predicted translation product of the only open reading frame between mxaR and mxaA. The protein sequence that is in italics and underlined represents the position of the start of the putative MxaS of P. denitrificans. The Mg-ATP-binding Walker motifs A and B are underlined. The consensus sequence of motif A is pXXXXXGXXGXGKT where p is a positively charged amino acid. The consensus sequence of motif B is RXXGXXXLfffD, where f is a hydrophobic residue. Asterisks indicate amino acids that are identical in the predicted proteins in P. denitrificans.

tion mutant in mxaJ is outlined in Fig. 1. The SalI site of pBR322 was removed by repair of cohesive ends with T4 DNA polymerase giving pKA0. The 6.8 kb HindIII-BamHI fragment of a pVK100 derivative, containing the mxaFJGI operon [18], was

cloned into pKA0, giving pKA1. To construct the mxaJ deletion, the 0.6 kb SmaI fragment of mxaJ was replaced by the kanamycin resistance gene from pUC4-KIXX [19]. This kanamycin resistance gene cassette was chosen because it did not contain tran-

scription terminators which would otherwise prevent transcription of mxa genes downstream of mxaJ. The orientation of the kanamycin resistance gene was determined by restriction digests with Bg/II (Fig. 1). A clone carrying a kanamycin resistance gene which would be transcribed in the same direction as mxaFJGI was selected to construct the mutant.

Using the EcoRI site in the pBR322 sequence immediately upstream of the HindIII site which was used to construct pKA1, the *Eco*RI-*Bam*HI fragment from pKA1 (ΔmxaJ::kan^r) was cloned into the suicide vector pRS415, a pBR322 derivative, which cannot replicate in M. extorquens. The resulting construct, pKA415J, was first transformed into E. coli TB1, to confirm that clones still expressed the plasmid-borne lacZ gene, and then mobilised into wildtype M. extorquens AM1 from E. coli S17-1. Transconjugants were plated onto methanol medium containing kanamycin and X-gal to select for colonies which had arisen as a result of integration of the plasmid into the chromosome by a single crossover. These were then streaked onto nutrient agar containing kanamycin and X-gal to identify Lac clones in which the vector and wild-type mxaJ gene were subsequently lost by a double crossover. Twelve pink, kanamycin-resistant colonies which were unable to grow on methanol were isolated and Southern blotting of the chromosomal DNA from one of these clones confirmed that 0.6 kb had been deleted from the mxaJ gene and replaced by the kanamycin resistance gene.

Mutant KAJ7 had the growth properties expected of a mxaJ mutant; that is, it was unable to grow on methanol but could utilise methylamine as sole source of carbon and energy. Whole cells oxidised formaldehyde, methylamine and pyruvate, but not methanol. Extracts contained no methanol dehydrogenase as determined in the dye-linked assay, and neither the α nor the β subunit of this enzyme was detected by Western blotting. However, both haem staining and Western blotting showed that cytochrome $c_{\rm L}$ was present in the mutant at wild-type levels, demonstrating that genes downstream of the deletion could be expressed. The absence of the \beta subunit is consistent with previous observations which suggested that its very small size (8.5 kDa) rendered it unstable in the absence of the large α

subunit [3]. The phenotype of mutant KAJ7 is quite different from that of the P. denitrificans mxaJ deletion mutant which synthesised the a subunit of MDH and also the β subunit and cytochrome c_L (albeit at decreased levels). By contrast, both the mxaJ transposon mutant of M. extorquens [10] and mutant KAJ7 failed to produce the a subunit of MDH. It is unlikely that MxaJ has a substantially different role in these two methylotrophs and our data are not inconsistent with the suggestion that this protein is involved in the processing of MDH [5]. However, it does appear that the \alpha subunit of MDH in M. extorquens is unstable in the absence of MxaJ. In P. denitrificans the newly formed MxaF and MxaI polypeptides may be intrinsically more stable, or another protein may be able to take over part of the function of MxaJ.

3.2. The DNA sequence between mxaI and mxaA in Methylobacterium extorquens

The sequence of the 2 kb BamHI-HindIII fragment which lies between mxaI and mxaA in M. extorquens has been deposited in the EMBL database (accession number Y07864); it overlaps a small amount of previously published sequence downstream from mxaI [20] and upstream from mxaA [9]. This completes a 11 801-bp sequence and demonstrates that their are two putative reading frames between the mxaFJGI cluster and the mxaACKLD cluster in M. extorquens. The predicted amino acid sequence of the first ORF has 60% identity with MxaR of P. denitrificans (Fig. 2). There is no obvious signal peptide or hydrophobic membranespanning regions, and the sequence indicates that MxaR (38.6 kDa) is a typical cytoplasmic protein. As no other proteins in the databases have significant homology with MxaR from these two organisms, the only information regarding its function which can be deduced from its sequence is the presence of two motifs relevant to MgATP binding. The first of these is the glycine-rich P-loop (Walker A sequence) [21] involved in binding ATP or GTP; the second motif is also found in some ATP-binding proteins but not in GTP-binding proteins [21]. It can reasonably be concluded, therefore, that the MxaR protein has a function involving binding ATP. The properties of a mxaR insertion mutant of P. denitrificans suggest that it may be involved in the processing of MDH in the cytoplasm, or in the regulation of other mox genes [5].

Our sequence indicates that in M. extorquens there is a single open reading frame after that encoding MxaR, which would code for a protein of 22.3 kDa. The C-terminal part shows 37% identity with the putative MxaS of P. denitrificans but there was no similarity to any other protein in the databases (Fig. 2). In M. extorquens, in the 228-bp region at the start of the putative ORF, the codon usage is completely atypical and the extra predicted 76 Nterminal amino acids would show a remarkable and highly unlikely amino acid composition, containing high proportions of arginine and proline but no glutamate and very little lysine (Fig. 2). Clearly this is not a coding region. There is, however, no initiation codon (ATG or GTG) in the sequence corresponding to the start of mxaS in P. denitrificans. This is unlikely to be due to a mistake in sequencing because the whole of the 2 kb were sequenced on both strands by both manual and automated sequencing, in duplicate. In the absence of any other evidence, the nature of the sequence identified as mxaS in M. extorquens should be interpreted with caution and we have consequently placed mxaS in parentheses in the sequence of genes proposed for this coding region. The sizes of the genes and intergenic regions (in parentheses) in the mxaFJ-GIR(S)ACKLD cluster are shown below (values here are for *M. extorquens*):

The genes form two well-defined groups in both M. extorquens and P. denitrificans. The intergenic regions in the first half of the cluster (between mxaF and mxaR) are relatively large (105–261 bp), whereas those in the downstream half (between the putative mxaS and mxaD) are very small (0–8 bp). This draws attention to the possibility that this whole cluster might be organised into two operons. However, there is no obvious promoter between mxaR and mxaA and further work is required to ascertain whether or not the mxaFJGIR(S)ACKLD cluster constitutes more than one transcriptional unit.

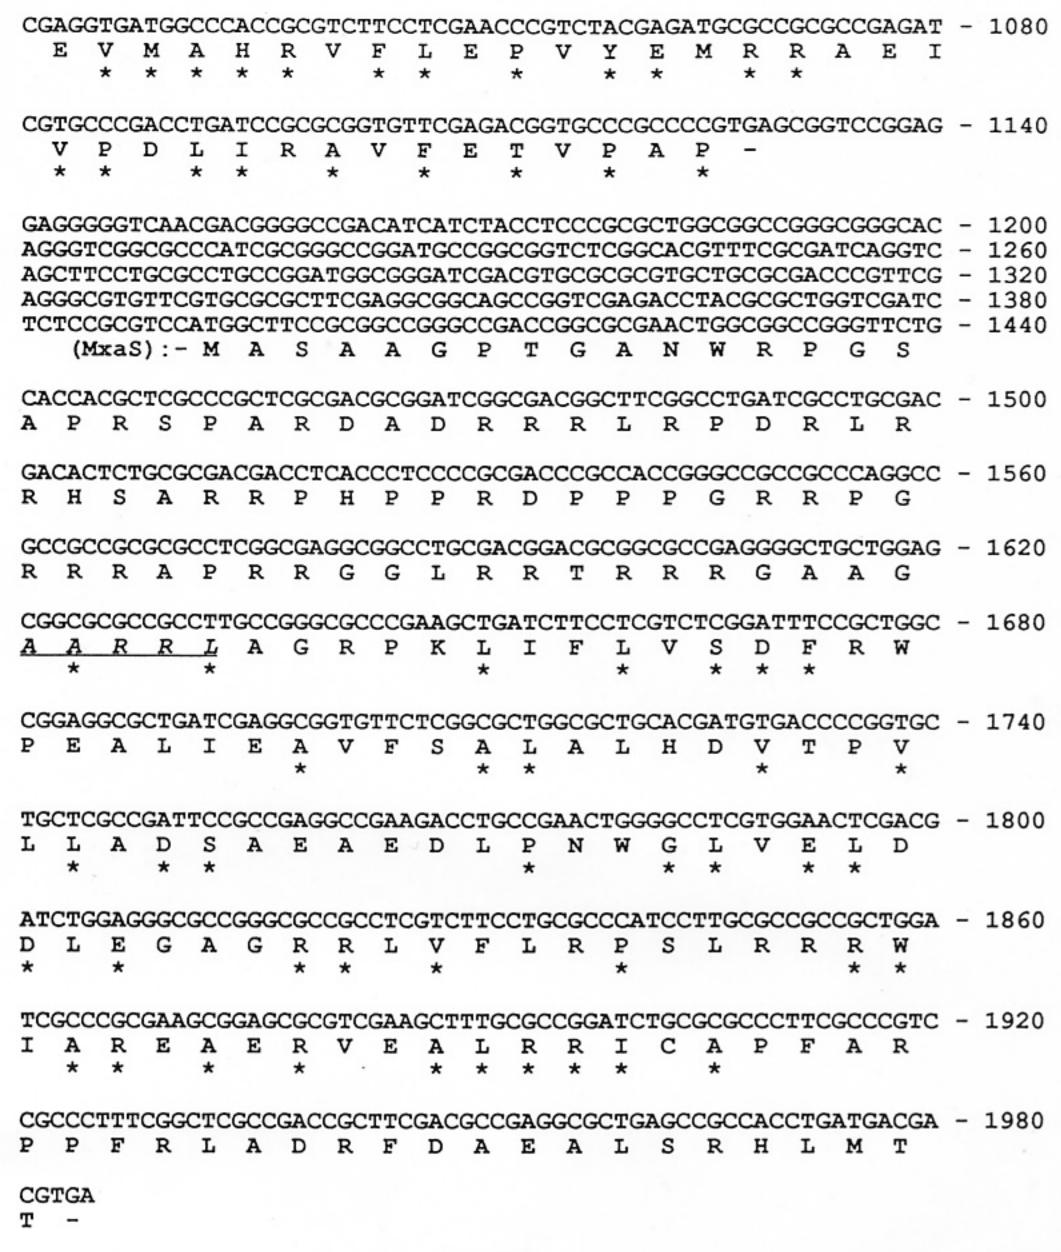

Fig. 2. The nucleotide sequence of the region between mxaI and mxaA in M. extorquens. Nucleotides 1–344 and the sequence downstream of 1886 have been described previously [9,20]. A possible Shine-Dalgarno site upstream of mxaR is underlined. The protein sequence labelled in parentheses (MxaS) represents the predicted translation product of the only open reading frame between mxaR and mxaA. The protein sequence that is in italics and underlined represents the position of the start of the putative MxaS of P. denitrificans. The Mg-ATP-binding Walker motifs A and B are underlined. The consensus sequence of motif A is pXXXXGXXGXGKT where p is a positively charged amino acid. The consensus sequence of motif B is RXXGXXXLfffD, where f is a hydrophobic residue. Asterisks indicate amino acids that are identical in the predicted proteins in P. denitrificans.
